1. About this Technical Paper

This Technical Paper has been prepared by the Superannuation Projections and Disclosure (SPD) sub-committee and the Retirement Incomes Working Group of the Actuaries Institute.

This Technical Paper does not represent a Professional Standard or Practice Guideline of the Institute. It has been prepared for the purpose of informing Members of issues in developing tools and calculation models that assist with retirement strategy design and planning decisions. The Institute is inviting comments and feedback from members in expectation of developing this Technical Paper into a Practice Guideline within three years of the date of publication of this Technical Paper. Please email the Professional Practice Documents inbox: ppd@actuaries.asn.au.

The Superannuation Projections and Disclosure sub-committee presented a draft set of principles for retirement modelling at 'Insights' sessions in Melbourne and Sydney in 2016¹ and version 1.0 at an online session on 23 August 2021. Feedback from those sessions was publicised in an Actuaries Digital article² and has been incorporated into this version. The original paper for this work was presented by Jim Hennington and Glenn Langton at the Actuaries Summit in 2016 and can be downloaded from the Institute's website³.

This Technical Paper does not constitute legal advice. Any interpretation or commentary within the Technical Paper with respect to specific legislative or regulatory requirements reflects the expectations of the Institute but does not guarantee compliance under applicable legislation or regulations.

Accordingly, Members are encouraged to seek clarification from the relevant regulator and/or seek legal advice in the event they are unsure or require specific guidance with respect to their legal or regulatory obligations.

Members are expected to refer specifically to the following Professional Guidance and ASIC regulations:

- Actuaries Institute PG 499.02 – Retirement Benefit Projections
- ASIC Instrument 2022/603 – Superannuation Calculators and Retirement Estimates
- ASIC RG 276 – Superannuation Forecasts: Calculators and Retirement Estimates
- ASIC RG 255 – Providing Digital Financial Product Advice

The Technical Paper does not override the requirements in these documents or in any other Professional Standards, Practice Guidelines or other Regulatory Standards that are relevant to this area of work.

¹ <https://actuaries.asn.au/knowledge-bank/past-events/2016>

² <https://www.actuaries.asn.au/research-analysis/why-we-need-to-lift-the-current-standards-of-retirement-modelling>

³ <https://content.actuaries.asn.au/resources/resource-ce6yyqn64sx3-786882053-11777>

A Document Control Box is included at the end of the document.

In this Technical Paper, when it says models “should” do something, it means the providers of the models “are encouraged to” do something. This is not implying a mandatory requirement such as what is considered in a Professional Standard.

2. Background – Retirement Modelling

Financial risk and decision-making that used to be shouldered by governments, employers and financial services providers have increasingly been transferred to individuals. This is a global trend and is referred to by The Institute and Faculty of Actuaries in the UK as The Great Risk Transfer⁴.

Consumer and behavioural research show that individuals are often not equipped to deal with the complexity of the decisions required of them. A household’s ultimate retirement income will often come from multiple sources and involves complex decision making.

Superannuation is the second largest asset most people will ever own and generates about half the income received by retired Australians. Deciding how to draw down from superannuation is particularly complex, especially for the over 840,000 Age Pensioners (about a quarter of those over 65) who are currently impacted by complex means tests. They can receive highly erratic cashflows because the amount of a part Age Pension varies considerably with the value of the pensioners’ assets rather than the amounts they draw down. Despite this, only a minority of Australians currently engage with a financial planner.

The government and ASIC⁵ believe technology has the potential to help bridge this advice gap. Examples of this are online calculators, projection tools used by planners and digital advice systems. While this TP focuses on the models behind these tools, the principles are relevant to the user interfaces and the documents they produce, which are the artefacts subject to regulatory scrutiny.

Australia is sometimes quoted as having the most complex retirement system in the world⁶. It is vital that the technology to help solve the advice gap meets very high standards. Like in other industries (such as health, automotive and construction) the public relies on highly trained experts to design infrastructure that is safe and easy to use but takes risk and complexity into account on their behalf. Consumers need to be able to trust the expertise of the professionals who build and maintain the infrastructure that we all depend on when making retirement planning decisions.

Actuaries are applied mathematicians who specialize in financial risk management. Actuaries are naturally placed to contribute to the setting of appropriate standards for modern retirement modelling. Retirement modelling involves assumptions about the future and differences in approach can lead to significantly different outcomes. A level of standardisation across the industry can help consumers. This Technical Paper includes a set of suggested 'Good Practice Principles' for Australia's diversified retirement modelling industry. Models are of little value unless retirees can have full faith that they have been built by and audited by appropriately qualified professionals who work to the highest ethical and professional standards.

These principles were developed to encourage good practice across retirement models developed in Australia. However, it is likely that some retirement models might not be able to meet all the principles below, e.g. due to the model's purpose or limitations in design. It is suggested that in such instances, model owners are encouraged to consider disclosing to their consumers the principles that have and have not been adopted, and the reasons for doing so.

The purpose of retirement models

Every Australian deserves a confident answer to basic questions like "How much do I need to retire?", "How much can I spend in retirement with a high level of confidence?" and "How much Age Pension can I expect to receive?" They also need to know how this will change if they contribute more/less to superannuation. However, the mathematics and assumptions to answer these basic questions with high confidence are surprisingly complex and deeply 'actuarial'.

The role of retirement models is to make sense of these decisions and to help people make informed choices. Households who aspire to a lifestyle in retirement that is higher than the Age Pension face significant uncertainty as they convert capital into retirement cashflows. To optimize a household's standard of living (and other objectives) they need to carefully consume capital over the course of their (unknown) future lifespans and through (unknown) market and inflation conditions.

Retirement models are needed by:

- **Retirees:** to make informed decisions about managing capital in retirement that takes into account the Age Pension and risk
- **Financial planning firms:** to ensure their advisers have the tools to model risk and retirement trade-offs in a prudential way that is on par with the standards used elsewhere in the financial services industry (e.g. where financial institutions manage their own risk exposures) and in other industries where consumers face risk
- **Superannuation funds:** to provide engagement / educational tools for their plan members, for product design and for member retirement estimates and advice
- **Regulators & policy makers:** for making policy decisions that affect retirees, as well as modelling the macro-economic impacts of retirement system settings and ensuring intergenerational fairness
- **Those who design products:** For example, adhering to the new Design and Distribution Obligations.

3. Principles for Retirement Modelling

The scope of retirement modelling can be broken down into four areas:

- People – which people, or groups of people are the subject of the model;
- Products – a product could be anything with a financial implication e.g. a salary, a super account, the Age Pension, a home loan, an asset;
- Goals – which goals (as measured by outputs) are in play and what key decisions do People need to make that impact those Goals, including constraints that need to be solved for; and
- Risks – which risks are considered, and what explicit or implicit assumptions are being made about those risks

Each of these scope points then may have attributes reflecting the level of depth to which it is modelled. The depth of model points are recommended to be proportional to the purpose of the model (e.g. you may not need to model the nuances of fees on a super account if the model purpose is to maximize a co-contribution).

The model itself can be thought of as having three main components:

- Data and assumptions – the inputs to the model
- Methodology – how the inputs are transformed into results
- Presentation – how the results are presented to the end user to compare against their Goals and empower decision making

The eleven principles that form the core of this technical paper reference the scope and model components described above. They are summarised in a practical checklist in section 5.

Principle 1: Retirement models should provide information and results that focus on the household's financial goals, the most important of which are their lifetime consumption needs and wants

It is recommended to make clear whether the household is a single individual or multiple individuals (e.g. a couple) and is recommended to cover the rest of their lives – both before and after retirement.

A good model requires being crystal clear about what the user is seeking to understand and/or the decisions they need to make. It is recommended that projections are provided together with relevant information relating to the user's goals in a form that is clear and easy to digest. It is recommended to focus on the most material issues that have an impact on the financial goal(s) of the household. The ultimate financial outcomes for a retired household are the spending they can enjoy over the rest of their lives including the course of their retirement and the value of their estate on death. There may also be needs for a lump sum to repay outstanding mortgages, for instance, particularly at the time of retirement.

Some aspects of a person's lifestyle (e.g. "needs" like food and shelter) are more important to them than others (e.g. "wants" like luxury holidays and new cars). Spending on wants is likely to be reduced in the event of poor market performance. Needs may require a level of precautionary savings to absorb fluctuations in expenses and poorer investment returns.

The most important decisions and trade-offs for one household may be completely different to those of another. Retirees fall into very different segments – for example based on their wealth, family status or age group. This directly impacts the relative importance of the Age Pension in funding their lifestyle. It's also likely to impact other considerations such as downsizing or leaving a bequest.

A 'layering' of goals into needs and wants is an example of a simple framework to deal with priorities.

An alternative approach to goal layering is the application of utility functions which provide a 'scoring mechanism' to attempt to encode the objectives and preferences of a household and reflect the fact that some outcomes have a greater impact on the retiree than others. However, these can be difficult to calibrate for each individual household and can be difficult to explain to users to aid decision making.

Principle 2: Models should be able to demonstrate the variability of future outcomes to facilitate informed trade-offs

Surveys show that top concerns of people in retirement relate to the fear of outliving their savings. Poor market performance, inflation, spending too much or living longer than expected are commonly cited concerns.

Considering Retirement Income Covenant requirements for trustees to help an individual make an informed decision about balancing the level of income, risk of the income and accessibility, it becomes increasingly important for Members who prepare projections to start communicating the implication of risk to the individual in addition to the deterministic projection of expected retirement balance and income.

A risk measure such as a numerical confidence level or interval is explicitly permitted under ASIC Instrument 2022/603 for certain types of projections.

Models should include a risk measure such as the probability of falling short of the household's expected and necessary living standards and other consumption goals(s) or bequests with the aim to help an individual understand the implications of risk in assisting them making an informed trade-off between the three dimensions of level of income, risk and accessibility.

Using only fixed assumptions based on averages is not appropriate for individuals or households. Few people will actually get the average outcomes, and it is beneficial for them to be aware of their idiosyncratic risk (i.e. risks specific to them as an individual)⁷. Individuals who don't invest in guaranteed products (such as life annuities) need to understand the range of outcomes they face, and the probabilities of the outcomes falling outside the range. A good model is encouraged to also disclose the key implications of the range of potential outcomes to their retirement living standards and other goals.

Actuaries and quantitative investment specialists are well placed to fit distributions to random variables such as market returns, inflation and a household's (joint) lifespan. See Appendix 1 for an explanation of what an investment simulation model is and how it generates thousands of market sequences that can be used for stress testing. These techniques enable results to be presented with corresponding probabilities or confidence levels that are imperative for retirement decision making.

It is likely that users will value a smooth consumption path, but some models are likely to assume that consumption will be adapted depending on investment and emerging health experience. The outputs are encouraged to illustrate the effect of investment and mortality variability on year-to-year consumption. Strategies that allow for the possibility of exhausting the household's assets (such as determining level ABP drawdowns for the life expectancy plus a margin) are encouraged to suggest trigger points when it would be advisable to reconsider drawdowns in order to prevent such exhaustion.

Principle 3: Models are encouraged to be able to project all significant assets, liabilities and incomes at the household level

Unless the scope of a model is deliberately narrowed, it is normal to consider retirement modelling at the household level. This may be an individual, a couple or a family, but also includes the financial drivers affecting the household's retirement.

Such drivers include all superannuation accounts, paid employments, retirement income streams, investment assets, other assets, loans, debts, bequests, life interests, taxes, obligations and social security entitlements. Many of these 'products' will generate cash flows (positive or negative) that impact retirement savings and income. Some of these items are interdependent, particularly regarding social security.

As at March 2021, 2.6 million people (62% of the population aged 65 and over) received income from the Age Pension. 38% of those in the age range 65 to 69 received an Age Pension, rising to 82% of those between 80 and 84. 32% of all Age Pensioners received a part Age Pension, a number that has fallen from 41% in 2015⁸. The time dimensions can be explained:

- Younger age cohorts have a greater proportion of their working careers with the Superannuation Guarantee in operation

⁷ A stochastic approach to retirement income planning, John De Ravin, 2014

⁸ <https://www.aihw.gov.au/reports/australias-welfare/income-support-payments-for-older-people>

- As individuals get older and consume their savings, they are more likely to receive an Age Pension later on in life, although interestingly the proportion of retirees on an Age Pension declines over the age of 85 possibly as a result of the longevity of higher income groups.

Because of the materiality of the Age Pension for most Australian retirees, retirement models need to take into account all material factors that the Age Pension means tests consider. This includes:

Both spouses, and their ages	Home ownership status
All superannuation and non-superannuation savings	Any (part time) employment earnings
All income streams including annuities, defined benefit pensions or overseas social security income	The fact that on first death of a couple the rates, bands and thresholds change to those of a single household

Table 1: Retirement models are encouraged to project all material factors that impact the Age Pension means tests

Models that track all relevant products at the household level over time will provide more reliable outcomes than those that make high level assumptions about them. However, a careful assessment of materiality needs to be made as some products will have little impact on retirement outcomes.

Principle 4: Models are encouraged to consider all issues that will have a material impact on future outcomes so that informed decisions can be made

Often there is no ‘right’ answer and each retiree needs to make informed trade-offs around spending today versus certainty about their financial situation in the longer term.

Models are encouraged to consider the drivers of retirement outcomes detailed in Table 2 below and have the retiree’s objectives at heart. They are encouraged to focus on the most relevant decisions different retirees need to make and to help the retiree to determine what their retirement could look like under different sets of decisions.

There are nine major drivers of a household’s financial outcome in retirement, as follows:

Within the retiree’s control	Retiree has some influence	Outside the retiree’s control
Investment choice and product choice	Timing of retirement	Market performance
Spending level and ‘shape’	Undertaking part time work in retirement	Inflation

Accepting a different level of risk	Health and lifespan	Tax and social security rules
-------------------------------------	---------------------	-------------------------------

Table 2: Drivers of outcomes in retirement

There needs to be a distinction between:

- what the user needs visibility and control over;
- what the retiree needs visibility of but can just trust meets professional standards; and
- detail that retirees may not need to see at all but just assume meets professional standards.

Just like products from other industries (automotive, aviation, computing), most customers don't want exposure to the internal workings and complexities where engineers have needed to make complex judgement calls. They want to see enough detail to make the decisions they have to, but beyond that leave the detail to the experts and be confident that those experts are working to high industry standards.

For example, for a consumer facing tool, it is recommended that:

retirees can see, and be able to change	retirees can see and trust, but not change	retirees can trust, and only see if interested
<ul style="list-style-type: none"> • Their retirement age • Their consumption goals both now and throughout retirement (profiles of spending) • Their assumed investment risk profile and portfolio choice • Their household assumptions including single or couple, homeowner or not, other asset and income amounts outside superannuation 	<ul style="list-style-type: none"> • The range of outcomes they could experience with clear description of (a) the top of range probability and (b) the bottom of range probability • The likelihood of achieving certain outcomes • Fee assumptions • How inflation has been accounted for 	<ul style="list-style-type: none"> • Tax & legislative rules modelled including Age Pension modelling • Asset and demographic model assumptions

Table 3: What Retirees are likely to need to see, change or just trust

Where a retirement model is:

- used by a financial adviser to assist their client, or
- reviewed by an actuarial, investment or other adviser, or
- studied by any non-professional adviser (e.g. a friend or colleague of the client), or
- considered by a regulator,

the adviser or regulator needs to be able to carry out due diligence into the assumptions and methodologies used. They may be more likely to need to see and adjust more of the key assumptions. For retirees, there might be reasonable restrictions on the parameters. For instance, long-term real investment returns are unlikely to exceed 7% p.a net after taxes and expenses.

ASIC may require users to be able to adjust more assumptions than most customers are likely to want to in practice⁹. These requirements can be accommodated via appropriate user interface design so that interested users can do so but without overwhelming other users.

Principle 5: Retirement models for households who are still working are encouraged to take into account a household's ability to change its circumstances over time

A retirement model is encouraged to project the movement and interaction of a household's retirement assets and liabilities throughout a person's entire future lifetime. This might include both pre-retirement (accumulation) and post-retirement (decumulation).

In addition to projecting all significant assets, liabilities and incomes at retirement (per principle 3), a model is encouraged to also be able to illustrate¹⁰ how a household's total income at retirement may change if certain pre-retirement factors are varied, such as:

- Saving more/less in retirement assets (possibly not limited to superannuation)
- Altering investment mixes and product types across existing assets
- Fees and expenses underlying assets that are currently invested
- Retiring at different ages
- Taking career breaks or plans to work part-time for a period in retirement

⁹ See for instance ASIC Instrument 2017/206

¹⁰ Actuaries Institute Submission to the Retirement Incomes Review. <https://treasury.gov.au/sites/default/files/2020-02/actuariesinstitute040220.pdf>

Such factors may have a material impact on a household's income at retirement. It is important that households are aware of the actions they are able to take prior to retirement to adequately shape their retirement lifestyle expectations, including the resultant impact on their projected Age Pension income.

Principle 6: Models are encouraged to be able to provide year-by-year projections of expenditure and assets and be able to allow for changes in personal circumstances and expenditure levels in any future year to allow for dynamic behaviours

It is vital to identify and then model all drivers that materially impact future outcomes and could therefore impact the retiree's decisions. But there is little point to modelling detail that doesn't impact the retiree's outcome.

As spending patterns are likely to change over the course of retirement (e.g. active phase, passive phase then frail phase) and can include large one-off expenditures and/or inflows (like receiving an inheritance) models are encouraged to carry out year-by-year projections. These cashflow patterns are likely to impact on the Centrelink means tests and therefore have a knock-on impact on the household's income from the Age Pension.

Likewise, the retiree's chosen asset mix and product mix (e.g. lifetime income products) have a major impact on the range of outcomes they face in retirement. Retirees are naturally going to want to explore the impact of changing their investment mix to understand the impact this would have on the likelihood of achieving their desired outcomes.

Future cash flows need to be adjusted for inflation. It is common to base this on estimates of wage inflation before retirement and price inflation subsequently. Illustrations are encouraged to make clear what assumptions are being used.

Principle 7: Except where required by legislation, economic and investment assumptions are preferred to be set on a central estimate basis. Variability around the central estimate are preferred to be accompanied by disclosure on confidence levels

Central estimate is an estimate that represents an expected value over the range of reasonably possible outcomes. It is often referred as "expected value", "mean" or "average". Please note that central estimate may be calculated on geometric or arithmetic basis depending on how it is to be used.

Examples of these are:

- Assumptions for future market conditions including:
 - Average returns and other statistical properties for each asset class (standard deviation, skewness, cross-correlations, auto-correlation);
 - Whether and if so, how or what, kurtosis or regime-switching, has been allowed for; and
 - Interest rates and inflation and their statistical properties;

- Fees and Costs: including investment management fees, percentage-based administration fees and fixed fees. Where the projection is in respect of a specific product, the fee assumptions are encouraged to reflect the current charging basis (including any indexation or other increases) for the product;
- Taxes on investment returns are encouraged to be included at the current legislated rates; and
- Assumed changes to legislated bands, thresholds and payment rates for the Age Pension.

Principle 8: Models are encouraged to consider the range of uncertainty for an individual's/household's (joint) lifespan and include a realistic allowance for future mortality improvements

The prevalent superannuation product for retirement in Australia is the account-based pension - where all risks are passed through to the retiree. For households whose spending isn't fully covered by the Age Pension this product requires 'self-annuitisation' – where each individual attempts to convert capital to retirement income over an uncertain timeframe.

A difficulty is that each individual doesn't know how long their own lifespan will be (their idiosyncratic longevity risk) and therefore doesn't know how much they can safely draw from their account-based pension. For couples it becomes a joint-life question given that cashflow is needed for as long as either one of them is alive.

It is inappropriate to use average life expectancy for this modelling. A predictable number of retirees will live to age 90, 95, 100 etc. Actuaries can project how many people in a group will live to each age, but we can't tell each user whether it will be them! Each household therefore needs to plan using a timeframe that gives them a confidence level that they are comfortable with, which is unlikely to be just a 50/50 chance of outliving their planning horizon.

Models need to allow for the probability that some individuals will live to each age in the Life Tables and that for couples 'first death' is also random variable that impacts outcomes such as the household's level of Age Pension. Lifespan estimates are encouraged to include an assumption for future mortality improvements (systematic longevity risk) such as those published by the Australian Government Actuary

Models are encouraged to be able to allow for scenarios where the household invests in lifetime income streams (e.g. life annuities) to manage the risk and return trade-off for reducing longevity risk.

Ideally, they are encouraged to also take into account the individual's health/demographic factors that impact personal mortality rates over time. For example, smokers have shorter life expectancies but wealthier, white-collar workers who own their home are known to have life expectancies much higher than population averages. ABS statistics show a dramatic difference in life expectancies between the various Statistical Area Level 4 regions in Australia.

Principle 9: Models are encouraged to be able to facilitate annual reviews to take into account the household's actual experience

Markets rarely deliver anticipated returns, and people's health and circumstances change.

It is therefore important to consider what retirees might do when experience is better/worse than what they have anticipated. As per Table 2, a retired household's options for improving their financial situation are limited. The strongest 'lever' is likely to be to reduce their spending level, but it may be possible to work a little more.

An annual review provides the structure to consider changed circumstance and make appropriate changes.

An example of how a financial model can be used to conduct an annual review in the retirement phase is included in Appendix 2.

Principle 10: Models are encouraged to come with an easy, standardised summary of what has/hasn't been modelled and certain key assumptions

It is encouraged to make it quick and easy for a user to see and compare the depth and quality of different retirement calculators. However, retirement calculators are inherently complex, and the presentation of this information is recommended to have regard to the audience. A suggested approach is to focus on the most important assumptions - with particular care to highlight important elements that have not been considered.

Standardised disclosure of the following "key items", in a table format, would be desirable. For ease of comparison, it is also recommended to have all ten items to be numbered 1 to 10 as below:

1. Deflator
2. Retirement income sources
3. Retirement income strategy
4. Payment period or longevity/mortality basis
5. Net investment return
6. Legislative environment (including limitations)
7. Age Pension basis
8. Administration fees and costs
9. Insurance premiums
10. Indexation of contributions and deductions

It is recommended that all ten items would be included even though one or more items may not be applicable (i.e. the disclosure for them might be "nil", "not applicable or "not allowed for"). Members would normally use judgement to decide the appropriate extent and depth of the disclosure detail for each item.

Item	Disclosure	Comment	Example wording
1. Deflator	Wage- and/or price-based, or zero if in future dollars	This is critical for the interpretation of the results, and comparisons between models	<p>This calculator shows results adjusted for inflation, allowing for both price increases and improvements in living standards, or</p> <p>Future retirement income amounts have been adjusted for price inflation only, i.e. they don't allow for improvements in living standards</p>
2. Retirement income sources	Total projected income is from super and Age Pension or income from super only	If it's not a total income being modelled, it's not comparable with a total income benchmark like ASFA Comfortable or a replacement rate	<p>This calculator includes both your super and an allowance for the Age Pension in your retirement income</p> <p>This projection deals with income from your super which is only one aspect of retirement income for most Australians. You should also consider income from the Age Pension and other assets you have.</p>
3. Retirement income strategy	How retirement income is determined initially and each year	We need to explain whether retirement income is based on a replacement rate, an income standard, or a solved amount, and the way it is assumed to move from year to year	<p>We have assumed you draw 6% of your super balance each year</p> <p>We have solved for a total retirement income that will last for 25 years from retirement, indexed with wage inflation.</p> <p>We have assumed you move your superannuation into an inflation-linked life annuity at retirement.</p>

Item	Disclosure	Comment	Example wording
4. Payment period or longevity/mortality basis	<p>How is the payment period determined?</p> <p>What is the longevity/mortality basis?</p> <p>Whether personal health recognised?</p> <p>Have mortality improvements been allowed for? What basis?</p>	<p>The period may be determined as a specified number of years, as an estimate of life expectancy, as a percentile of longevity outcomes, or not allowing for mortality at all.</p>	<p>Calculator A solves for the level of income that your super could support over 25 years.</p> <p>Calculator B shows the level of income that could be achieved for your life expectancy plus 5 years.</p> <p>Calculator C shows how much income you could live on with 90% confidence of not outliving your income.</p> <p>Calculator D does not assume a payment period, but shows how long your chosen level of income could last.</p>
5a. Net investment return (I.e. net of all investment fees and costs and net of tax)	<p>Returns and asset allocation for both accumulation and retirement phase.</p> <p>The basis for setting returns as long-term estimates, or market-aware, central estimates or inflation plus objective etc.</p> <p>While this paper states a preference for central estimate, other common practice may be used by Members. It is important that the basis for setting the returns is disclosed clearly.</p>	<p>The assumed investment return should be a central estimate* and should be consistent with the inflation rate assumed</p> <p>*Different funds may have different ways in determining their estimate of investment return. Some may use the same figures as their CPI plus investment objectives stated in their PDS but most often these are set based on say a 2/3 probability rather than a central estimate that is closer to 50%.</p>	<p>The default investment return for pre-retirement is based on a Balanced fund: using 7% p.a. net of super tax and investment fees.</p> <p>The default investment return for post-retirement is based on a Moderate Growth fund: using 6% p.a. net of investment fees.</p> <p>Expected average price inflation: 2% p.a.</p> <p>The returns quoted above are gross of any asset-based administration fees.</p>

Item	Disclosure	Comment	Example wording
5b. Stochastic investment returns	<p>As for 5a plus:</p> <p>The investment simulation model used, the basis for the simulations and key metrics e. g. means and risk metrics for the main asset classes.</p>	<p>Needs to be appropriate for the purpose of the model being used.</p> <p>Sometimes historical illustrations may be more appropriate than stochastic simulations.</p>	<p>The model uses 5,000 inflation and market simulations obtained from XYZ company. The simulations are calibrated to illustrate the range of future outcomes a retiree may experience. Fees and taxes are applied separately</p>
6. Legislative environment (including limitations)	<p>The rates, thresholds, caps applying noting any measures not allowed for</p>	<p>This could be “Legislation applying for the 202x financial year”. But things like the phased increase in SG needs to be disclosed even if not applying in the current financial year</p>	<p>This calculator applies the legislative environment as at 1 July 2019, but does not allow for the temporary reduction in minimum drawdown requirements</p> <p>This calculator has been created to model proposals outlined in the Federal Budget which have not yet been legislated</p>
7. Age Pension basis	<p>Single/couple rate, age/super balance of partner, homeowner status, other assets</p>	<p>Based on current legislation, indexation of the base Age Pension should be linked to the greater of inflation or wages and there is no indexation of supplements. Likewise, indexation of means test thresholds should be based on price inflation.</p>	<p>The calculator applies the current Age Pension payment rates for a single person, and the means tests assuming you will be a homeowner at retirement with \$50,000 in other assets</p> <p>This projection assumes you are partnered at retirement, your partner has the same amount of super and you are homeowners with no other assets</p>

Item	Disclosure	Comment	Example wording
<p>Where relevant an additional illustration of alternative retirement outcomes to demonstrate other non-legislated Age Pension or threshold increase bases, might be provided.</p>			
<p>8.Administration fees and costs</p>	<p>The amounts assumed for asset-based and dollar fees</p>		<p>The calculator assumes an asset-based administration fee of 0.25% p.a. and a member fee of \$2.50 per week (indexed)</p> <p>The projection allows for an asset-based administration fee of 0.5% p.a., capped, initially, at \$400 p.a., and total dollar fees.</p>
<p>9.Insurance premiums</p>	<p>The amounts assumed for insurance premiums</p>	<p>Common practice takes current insurance premium charged and index to derive insurance premium charged in future years</p> <p>Depends on the complexity of different funds' insurance design, some may derive future insurance premium charged with calculation based on expected insurance cover and insurance cost per unit of cover</p>	<p>The projection allows for insurance premiums of \$600 p.a. (indexed)</p>

Item	Disclosure	Comment	Example wording
10. Indexation of contributions and deductions	Wage- or price-based, or zero		Voluntary contributions are assumed to increase with wage inflation. Insurance premiums and member fees are indexed with wage inflation.

Table 4: Standardised disclosure of key items

Other disclosure might include:

- Features that the model handles:
 - Spouse
 - Age Pension and means testing
 - Tax
 - Non-super savings and additional superannuation accounts
 - Other lifetime income streams (e.g. annuities, DB pensions, overseas pensions)
 - Part time employment income
 - Spending shapes and other goals
 - Ability to downsize the home or release equity.
- Complexities taken into account:
 - Market risk
 - Longevity risk
 - Personalised mortality assumptions
 - Joint-life longevity
 - Whether it takes into account current market conditions.

- Other quality control information:
 - Who stands behind the model
 - When the assumptions and rules were last updated
 - A note about status when key legislation changes (i.e. whether new rules have been taken into account)
 - Peer review undertaken
 - Disclaimers.

The ASIC Instrument 2022/603 and RG 276 set out conditions under which superannuation forecasts can be provided without an Australian Financial Services License. One of these is to include a clear and prominent explanation of the impact of any significant limitations of the calculator. It also requires a clear and prominent statement of the assumptions and why the provider considers the assumptions to be reasonable.

The ASIC regulation also requires a clear and prominent statement to the effect that a superannuation calculator or retirement estimate is not intended to be relied on for the purpose of making a decision about a financial product and that users should consider obtaining advice from an AFS Licensee before making any financial decisions. If there are some qualms about suggesting that people obtain financial advice, this requirement may be prefaced by: “ASIC requires providers to make the following statement.”

Principle 11: Models should be built to be easily updated as required to consider changes to assumptions and legislation

There are a range of rules and assumptions that retirement models take into account and which are subject to change over time so need to be maintained. This includes superannuation caps and thresholds, market expectations, inflator/deflator, mortality tables, improvement factors, age pension rules and other key legislation.

Best practice models would store all these parameters in a single repository that is straightforward to update and easy to access for verification purposes.

4. Checklist for retirement model development and assessment

The application of the eleven principles discussed above has been distilled into a checklist for practical purposes. The purpose of this checklist is to offer a comprehensive and user-friendly guide for evaluating the quality and effectiveness of retirement models. It is designed to help model owners and developers ensure that their models adequately consider all essential elements, aligned with the model's intended purpose. This checklist serves as a framework for design decisions regarding the inclusion or exclusion of specific elements during the development of retirement models. It also functions as a self-assessment tool applicable to both internal and external models, covering pre- and post-retirement phases.

Scope		Is the model scope appropriate for the purpose?	It should be clear what is in and out of scope for the model
1	People	Does the model allow for single people and households?	Retirement models should account for household circumstances
1.1	Primary	Are all relevant aspects of the primary user captured?	The model should capture current situation, and future preferences for the primary user, to the extent they impact the model outcomes. Where default values are applied, that these are brought to the attention of the user
1.2	Partner/ Dependants	Are all relevant aspects of the partner and dependants captured?	The model should capture current situation, and future preferences for the household, to the extent they impact the model outcomes

2	Resources	Does the model allow for all relevant financial resources?	Retirement models should account for all relevant resources
2.1	Salary	Are salary and wages from employment captured?	To the extent that total and household income are relevant, the model should cater for these including phasing, career changes, self-employment and potential work in retirement phase
2.2	Other income	Are non-employment income sources relevant and captured?	To the extent that non-employment income is relevant, the model should cater for this. This should include dividends, net rentals and other investment income, as well as DB pensions (being mindful of assumptions regarding indexation).
2.3	Super contributions	Are various types of super contributions included?	The model should account for all types of (such as employer, voluntary pre and post-tax), frequencies (such as ongoing annual, one-off) of super contributions.
2.4	Super account	Are all superannuation accounts included?	Where multiple super accounts are relevant, provision should be made for each one, or at least aggregation of DC accounts
2.5	Income stream	Are all relevant income stream options modelled?	Where specific lifetime or market linked annuities are offered by the calculator provider, they should be included. If not, a generic longevity option, or disclosure regarding the availability of such products, should be provided
2.6	Age Pension	Is the Age Pension modelled?	The Age Pension, including means test thresholds, taper rates, indexation, partner and homeowner status should be modelled

2.7	Non-super resources	Are non-super assets and debts included in modelling?	To the extent that non-super assets and debts have an impact on retirement (including means tests), they should be included in the model. They may be income producing assets, debts that need servicing/repayment, expected inheritances, or capital drawn for retirement purposes. The tax impact of accessing these non-super resources should also be covered at least in disclosure, if not in the modelling itself.
3	Goals	Is it clear which goals are in scope?	Retirement model outcomes should be driven by user goals and decisions
3.1	Approach	Is it clear to the user how the model handles retirement goals?	<p>Some models will use retirement income as an input/goal, and solve for a period it can be sustained. Other models will use a retirement period as an input and solve for the income that can be sustained over the period. Other models may take a longevity weighted approach, using neither a set income nor a set period as inputs, but rather a certainty metric.</p> <p>The model should explain to the user how to engage with their retirement goals and set clear expectations for the implications of the results.</p>
3.2	Income/ Spending/ Budget	Is the user able to set a total retirement income required from all sources?	Where retirement income is an input/goal, the model should allow the user to determine their total retirement income. It should be set as a current dollar amount or as a percentage of pre-retirement spending. For those already retired, it should focus on detailed spending. For those where retirement is some time off a ballpark total income approach is sufficient. The indexation of this income in retirement should be addressed as part of the retirement income goal, including whether the user expects increases in standard of living during retirement.

		Does the model address concepts of spending vs income, as an input or at least in disclosure?	Best practice includes a budget breakdown that interacts with the retirement income assumption used by the model, and the option to enter different goals for phases of retirement.
3.3	Lump sum	Is the user able to model multiple lump sum withdrawals?	The model should allow for lump sum spending on specific items such as mortgage repayments, travel, gifts, home alterations and cars.
3.4	Retirement period	Is the user able to set a retirement period?	Where retirement period is an input/goal, the model should allow the user to determine their retirement period, that is the target period for which a total target retirement income will be provided. This should be described in terms relative to their longevity expectations— jointly if appropriate.
3.5	Contingency fund/Bequest	Is the user able to set a goal for a contingency fund, or for a bequest/estate?	The model should allow the user to determine whether their total assets are sufficient for both regular and contingent needs at future ages
3.6	House purchase/rental costs	Is the user able to include savings for a home deposit, mortgage repayments and rental costs?	The model should allow for housing costs to the extent they impact retirement income. For example, a mortgage that is not paid off during accumulation phase will impact the resources available for retirement. Those who are renting in retirement may be eligible for Rent Assistance and will have different applicable means test thresholds.
3.7	Aged care	Does the model include the possibility of provisioning for aged care?	The need to consider later life care expenses should be discussed, but modelling at a product level is unlikely to be feasible. Users who wish to set an asset or income goal allocated to later life care can be catered to in advanced models.

4	Risks	Is it clear which risks are allowed for in the model?	Retirement models should address all relevant risks and their likelihood, to the extent that they bear on adequacy of retirement resources
4.1	Longevity	Does the model show a range of longevity outcomes?	The model should allow for cohort mortality improvements, and demonstrate the likelihood of outliving savings. If not modelled, then disclosure should discuss potential impact of outliving savings.
4.2	Mortality/ Disablement	Does the model allow for the risk of death or disablement?	The model should allow the user to explore contingencies on first death, or the impact of disablement on income and expenses. If not modelled, then disclosure should discuss mortality/disablement risks
4.3	Inflation	Does the model include price and wage inflation, and distributions of these?	The model should allow for the measures of inflation, consistent with asset returns, and their application to present values. If not modelled, then disclosure should cover inflation risks.
4.4	Market	Does the model include a range of outcomes for asset returns and their impact on expenditure?	The volatility of asset returns and their correlation with inflation, interest rates and currency movements should demonstrate the impact of market risk. If not a stochastic model, then disclosure should cover market and sequencing risks
4.5	Employment	Does the model account for employment contingencies?	The model should allow the user to explore service breaks, involuntary retirement. If not modelled, then disclosure should address potential impact of employment contingencies.

5	Assumptions	Are default assumptions reasonable for the model purpose?	Retirement models should use reasonable assumptions where data is unavailable
5.1	Economic	Are economic assumptions central, consistent and set within confidence bounds?	Deterministic assumptions should be central estimates by default, with the user being permitted to modify them within reasonable bounds. Modelling multiple economic scenarios is preferred, along with allowing the user to set a level of confidence over the outcomes.
5.2	Product	Are all relevant product related assumptions considered?	Product related assumptions cover fees, costs, premiums that are relevant to the product that is being modelled. If a specific product is modelled that offers investment options with target asset allocations, consideration should be given as to how these allocations interface with economic assumptions to generate reasonable option returns.
5.3	Mortality	Are mortality assumptions the best fit for the people modelled?	Models should allow for cohort mortality improvement
5.4	Behavioural	Are behavioural assumptions aligned with circumstances, preferences, goals and rationality?	The model should make reasonable assumptions about member behaviour in relation to tax efficiency, risk profile, rebalancing, and retirement choices. Some examples include, claiming the Age Pension, rebalance portfolios on a regular basis, treatment of excess income drawn due to minimum requirements, contributing within caps, etc.
6	Methodology	Are calculations logical, consistent and reasonable?	Retirement models should use methodology appropriate to the outcomes

6.1	Time	Does the model treat time in a realistic way?	Some models may project cashflows based on financial years and may treat the first part of the year differently. Any such treatment should be reasonable, appropriate for the purpose and clearly disclosed.
6.2	Cashflows	Is the timing and tax-status of cashflows reasonable?	Contributions, expenses, tax, drawdowns and other cashflows should be reasonable for the purpose
6.3	Environment	Are all relevant details about the regulatory and legislative environment captured?	The model should apply relevant tax rates and thresholds, minimum drawdown requirements, contribution and benefit limits and access conditions
6.4	Investment	Are assets and earnings appropriately categorised for growth, tax and availability?	Super and other assets (including debt) should be treated according to attributed asset models and legislative provisions
6.5	Indexation	Are cashflows indexed reasonably?	Indexation of fees, expenses, lump sums, income, drawdowns etc should be consistent with assumptions
6.6	Dependencies	Are all cashflows and asset values used consistently for relevant purposes?	Where quantities are used for multiple purposes (e.g. assets for means test and retirement income purposes), consistent treatment should be applied
6.7	Stochastic method	Are stochastic methods based on reasonable parameters and summary statistics?	If stochastic analysis is applied, the model should correctly disclose underlying assumptions the modelling is based on (e.g. using historic data, or a bottom-up economic simulation). Analysis should be based on cashflow outcomes, and consideration should be given to the illustration of sequencing risk.

			Any result metrics used such as percentiles, confidence score, downside risk should be explained at a level appropriate for users.
7	Presentation	Is the user interface clear so that results are not misleading?	Retirement models should present outcomes and disclosure to satisfy both regulation and user needs
7.1	Purpose and limitations	Are the model's purpose and limitations clear?	The model should provide a prominent statement of purpose and limitations
7.2	Inputs	Are all inputs explained in terms a target user would understand?	The model should identify inputs and assumptions in the language of the user
7.3	Outputs	Are all model outputs explained in terms of a target and range that a user would understand?	The model should identify outputs and conclusions in the language of the user and in a way that helps users assess whether they can meet their Goals. A model should provide evidence of the year-by-year outcomes at a high level at least.
7.4	Iterations	Are users able to adjust the inputs until they are satisfied with the outputs?	Models should facilitate iteration – and assist users to explore the key decisions they need to make that will impact their Goals - both initially and when circumstances change. If appropriate, users should have the ability to print the results in an accessible format or to save the results and return to them.
7.5	Feedback	Does the model allow for feedback from the user and from experience as time passes?	If the model is intended for revisiting, it should prompt the user to confirm accuracy of saved data

7.6	Precision	Is the precision of outputs appropriate to the uncertainty of the results?	Short term results should be shown with greater precision, while less certain results especially long-term projections should be rounded and shown in probabilistic terms
7.7	Disclosure	Is there a clear explanation of the assumptions and methodology employed by the model?	The model should provide sufficient information for an informed expert to be able to check results independently
7.8	Practicality	Is the model secure, usable, reliable, educative and able to crystallise results into a document?	The model should be user-centric and practical to use, including sufficient guidance (glossary, tutorial, explanations) and a means for the user to create a document that includes all the relevant inputs and results, with appropriate disclosure to understand them.
7.9	Compliance	Does the model meet regulatory requirements?	The model should comply with all relevant regulations
7.10	Context	Is the model presented in an environment that promotes its optimal use and understanding?	The model should reside within a user journey that establishes the need for a model, explains the scope and framing of the model, key terms used in the model and makes it clear how to act on the results of the model.

Appendix 1: Investment Simulation Models (ISMs)

An Investment Simulation Model (ISM) (also known as an Economic Scenario Generator (ESG)) is a software tool that generates a collection of simulated economic scenarios that represent a full distribution of possible economic futures. ISMs are commonly used by large financial organisations to support risk management, reserving and pricing activities. The theory and science behind ISMs has evolved considerably as computer power has increased and the field of Quantitative Analysis has developed.

The collection of simulated scenarios from an ISM can be used to 'stress test' a financial entity through a plausible range of future market outcomes. Provided the probability distributions used within the ISM are appropriate, we can use the collection of scenarios to map out the range of outcomes a given financial entity faces based on its own exposures to the various risks. For example, to satisfy Europe's Solvency II legislation insurers must demonstrate that they can withstand a '1 in 200-year market event.

When simulations from an ISM are used in a financial model this is often referred to as a stochastic model (compared to those that use only fixed return assumptions).

Improvements in the methodologies used to model risk make it possible for households to quantify issues to a deeper level than was common practice even a decade ago. Sophisticated stress testing tools can be applied to retirement modelling for individual households. This can help retirees align their financial planning decisions (e.g. spending levels) with the level of confidence that suits their risk preferences. Some retirees might want a very conservative approach and if account-based assets were used, require a large buffer of savings relative to spending level. Alternatively, they might choose a guaranteed life annuity where the company issuing the annuity held capital (which would be smaller because of diversification benefits). These strategies would result in a cautious lifestyle that was, on average, below what they might otherwise enjoy. Whereas other retirees may be willing to accept that if a 1 in 20-year market event were to occur then their retirement lifestyle could end and they'd live solely on the Age Pension. This decision may let them enjoy a better lifestyle providing they remain in a lucky cohort who do not experience that 1 in 20-year event. Suitable explanations about the implications of risk decisions are required.

ISM software lets the modeler simulate a full range of factors driving market risk. A good ISM is a coherent, integrated Monte Carlo generator that produces realistic scenarios. If not arbitrage-free, the modeler needs to be able to explain why¹¹. The scenarios include a variety of metrics including interest rates, credit spreads, equities, property and exchange rates, each with a carefully chosen and calibrated probability distribution. The model needs to consider:

- Means for each asset class (often time varying), taking into account starting market conditions;
- Standard deviations that may also be time varying

¹¹ For evidence that regulations and shortage of capital can leave significant apparent arbitrage opportunities see Du, W., Tepper, A., & Verdelhan, A. (2018). Deviations from covered interest rate parity. *The Journal of Finance*, 73(3), 915-957.

- Correlations (including both cross correlation and auto correlation); and
- Tail distributions.

The ISM is likely to incorporate an analysis of theory, history and current market conditions as well as having an element of subjective judgement when setting expectations for the future. It needs to be able to produce some extreme but plausible results and generate scenarios that embed realistic market dynamics. Often large teams work on maintaining an institutional ISM and will work with an investment committee to review and update approved assumptions as market conditions and expectations evolve.

Often the models are built up from a primary metric such as global inflation. Inflation in any year is typically assumed to be a function of (a) inflation in the previous year, (b) an assumed long-term rate of inflation and (c) a random element consistent with the distribution assumed. Local inflation is likely to have linkages to both global and past local inflation plus a random element.

Bond yields might assume a process with linkages to global inflation and previous years' yields both globally and locally. A yield curve is typically constructed from short and long rates meaning that bonds of different maturities can be modelled concurrently.

Equities might reflect a Capital Asset Pricing Model (CAPM) structure with distributions that capture an assumed shape for the tails. Assumptions for skewness and kurtosis should be consistent with what is seen in actual equity markets. Exchange rates typically incorporate a Purchasing Power Parity approach and each future year would normally depend on the previous year.

For each of these variables, models should produce results that credibly reproduce the tails. short-term momentum and mean reversion observable in investment markets. Graphs provide a good way to compare. The graph below is taken from Andrew Smith's chapter in the Actuarial Control Cycle textbook Understanding Actuarial Management. Illustrations of extremely poor outcomes should be compared with the investment and inflationary experience of the 1930s and 1970s.

Figure 9.4 Simulated path using independent normal variables

Availability and consistency of ISMs

Developing ISMs is a specialist field. Actuaries are well placed to accurately use ISMs within good retirement models. Actuaries can also help to interpret and explain outcomes from stochastic retirement models (such as defining 'high' confidence as results that occur with at least an X% probability).

Whilst the cost of building an ISM can be high, there are a number of specialist firms who provide services in this area as well as a number of ISM models used in academia. For a list of known providers, please contact the Actuaries Institute.

ISMs are often used overseas, including the USA and Europe. An issue that can arise is that it isn't easy to compare two ISMs or to check the consistency between models. This results in a risk that the choice of ISM could mean different conclusions are reached when comparing one retirement strategy against another. As an industry, such differences are recommended to be avoided if possible. Whilst the documentation on the underlying method and assumptions used in an ISM can be reviewed, in practice it will be hard to determine if the data is reasonable, especially at the tails - where appropriate calibration can be difficult due to scarcity of data.

A potential industry approach to overcome this consistency problem is to develop a calibration test for which all ISMs should generate the same results, within a statistically tolerable margin of error. This approach has been used successfully in the field of solvency and capital requirements globally, where the insurance or banking regulator allows a financial entity to use their own internal models to set capital requirements with the requirements that certain statistical calibration points be met.

The importance of ensuring that ISM assumptions are appropriate was touched on by the Australian Government Actuary (AGA) and Treasury as part of the 2019 Retirement Income Disclosure Consultation which included the AGA's proposed Retirement Income Risk Measure¹².

Page 10 of Treasury's Consultation Paper said:

"Income variation risk measure consultation

If the proposed method of calculating risk is adopted, further consultation would occur on the model to be used and associated assumptions on various asset classes, their returns, correlations and volatility; including collaboration with the AGA, industry and investment model practitioners."

Models utilising data from ISMs also need to be updated regularly as the economic environment changes. The cost to obtain data sets each time can be upward of ten thousand dollars. In other industries (food, health, aviation, automotive) the cost of ensuring safety of customers when building infrastructure is regularly at these type levels. Retirement models impact millions of Australians. The benefits of taking risk into account more than justify these relatively small costs.

¹² <https://treasury.gov.au/consultation/c2018-t347107> See page 18 of the AGA paper and page 10 of Treasury's paper.

Appendix 2: Annual Reviews to take into account Actual Experience

An example of how a retirement model may be used to facilitate annual reviews that take into account the household's actual experience:

First year:

1. Obtain current values of all financial resources
2. Identify the household's goals (e.g. essential lifestyle pattern) throughout their future retirement
3. Use the model to confirm that there is a very high probability this essential lifestyle can be achieved for life, in light of the full range of possible future outcomes
4. If not,
 - enable the user to consider alternative products and/or strategies with the aim to achieve the original goal
 - adjust their expectations (which may involve downsizing the home and/or reducing what is categorised as essential)
5. If so,
 - then use the model to explore what level of discretionary expenditure the retiree can reasonably aim for in addition:
 - Start by assessing their total desired expenditure patterns throughout retirement
 - Adjust this expenditure so that the chosen pattern can be achieved using 'central estimate' assumptions.

Future years:

1. Check the actual experience the retiree has seen over the past year, including:
 - a) Investment returns
 - b) Inflation
 - c) Actual asset mix
 - d) Actual spending levels
 - e) Changes to legislative rules (including the Age Pension level and thresholds)
 - f) Changes to family situation

g) Changes in health status

h) Changes in needs including what's considered essential going forward

Note: a to d would have likely been reflected in the updated asset level for the new year already.

Revisit and update the assumptions including all of the items in (1) above as well as assumed future mortality rates and legislative rules.

Repeat the above 'first year' process.

Appendix 3: Examples of innovation to explain retirement results to consumers

This appendix shows examples of emerging innovation in the area of communicating retirement outcomes and the impact that key household decisions have. The examples come from a range of different providers.

The examples are only 'taster' screen shots and are shown for information only. They may not meet all of the Principles in this Technical Paper. They have been included for the purpose of showcasing the growing range of possibilities for user-interface design in this area. Before drawing any conclusion about the strengths and weaknesses of any example, please note that we have only included a screenshot that comes from a broader user-journey which is likely to include more education and explanation about what the results mean, how to interpret them and disclaimers about any limitations.

For further information about any of the examples, please contact the provider of that particular calculator.

Example 1

Range of projected balance over the lifetime (to and through retirement) and one selected scenario, based on *Austmod*¹³ simulation outcomes.

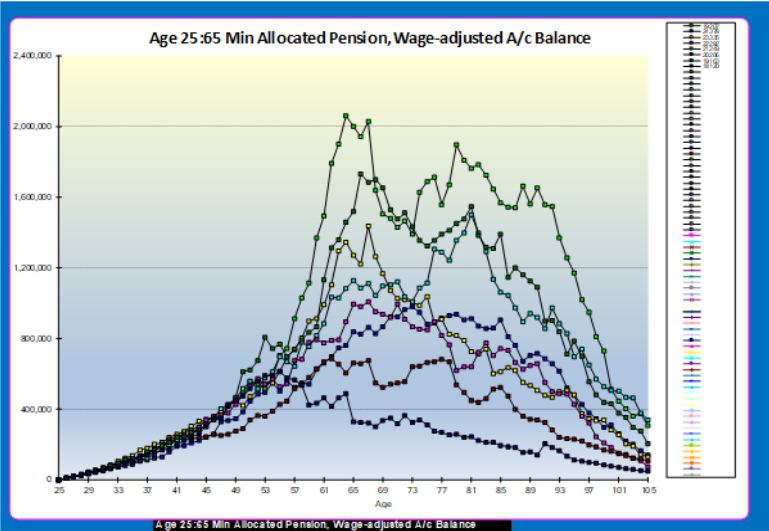

¹³ All *Austmod* scenarios are from Colin Grenfell's *Austmod* stochastic and historical investment simulation model. The projections illustrated assume the minimum is drawn from an account-based pension.

Range of projected net cashflow from superannuation through retirement and one selected scenario, based on *Austmod* simulation outcomes.

Range of projected balance over the lifetime (to and through retirement) based on eight selected *Austmod* scenarios.

Range of projected income through retirement based on eight selected *Austmod* scenarios.

Further information about *Austmod* and the assumptions used is in "*Australian Investment Performance 1959 to 2021 (and Investment Assumptions for Stochastic Models)*"

Example 2

Using historical scenarios

There are four scenarios on each page. Move the slider to get a level of spending and volatility across the scenarios that most satisfies you.

The scenarios are based on actual investment returns, after allowing for inflation. They go back over a century so that we can illustrate what you would have spent if you lived to 95. The last graph shows returns as if you were born in 1919 and died in 2014. The other scenarios show what would have happened 5, 10 and 15 years earlier. Future investment returns will be different to the past, but the past gives us the best illustrations of the volatility of returns that we have, and therefore gives the best indication of possible changes to spending.

The approach to investments on this page involves choosing a level of risk that changes the relative mix between shares and interest bearing investments. The bottom graph shows the proportion in shares, with the rest being in interest bearing investments. In the middle range of risk, the proportion in shares reduces as you get older and are less able to bear risks.

Spending if you had been born in 1904

Spending if you had been born in 1909

Spending if you had been born in 1914

Spending if you had been born in 1919

Proportion of Investments in Shares

Slide to choose an optimal investment and spending strategy.

Example 3

Range of projected retirement outcomes. Two examples from the government's BETA team research which tested a range of approaches on 3,600 pre-retirement members from five industry and retail superannuation funds¹⁴

	Plan A	Plan B
Amount of income	This plan provides a medium-to-high amount of income Expected average fortnightly income is: \$843	This plan provides a low amount of income Expected average fortnightly income is: \$667
Protection from running out of income	This plan provides you with high protection from running out of income	This plan provides you with high protection from running out of income
Amount of money available for lump sum withdrawals or bequests <small>Note: if you withdraw a lump sum amount during your retirement, your fortnightly income will subsequently be lower</small>	This plan provides a low amount of money for lump sum withdrawals or bequests Expected average amount of reserve money available is: \$41,000	This plan provides a high amount of money for lump sum withdrawals or bequests Expected average amount of reserve money available is: \$173,000
Protection from fluctuations in income	This plan provides low-to-medium protection from income fluctuations due to changes in investment returns (positive or negative) In most years, income could rise or fall by: 4.5%	This plan provides low protection from income fluctuations due to changes in investment returns (positive or negative) In most years, income could rise or fall by: 6.7%

Comparing retirement product projections using risk metric proposed by the Australian Government Actuary¹⁵

¹⁵ Risk metric proposed by the Australian Government Actuary as part of Treasury’s Retirement Income Disclosure Consultation. “Retirement Income Metric” December 2018 <https://treasury.gov.au/sites/default/files/2019-03/Retirement-Income-Risk-Measure-FINAL-Consultation-1.pdf> p18

Example 5

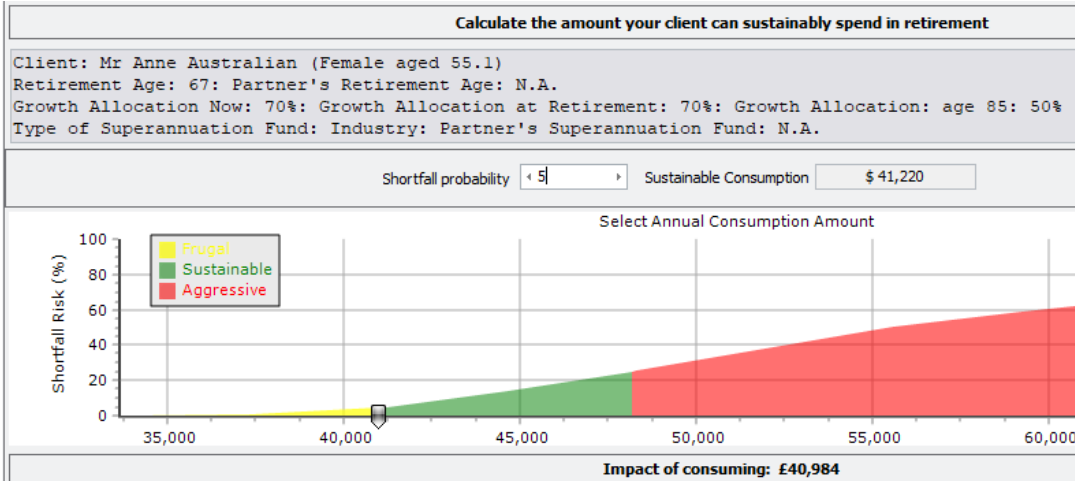

Testing projected outcomes using likelihood of achieving goals¹⁶

The screenshot displays the 'Personalize Your Plan' interface for Dimensional Managed DC. At the top, there is a navigation bar with the logo, language options (Nederlands, English), the date (18 March 2011), and user information (Welcome MDC Tester, Log out). Below the navigation bar are buttons for 'Your Plan', 'Edit Plan', and 'Help Center'. The main content area is titled 'Personalize Your Plan' and includes a sub-header 'Watch a video on personalizing your plan'. A descriptive text states: 'Move the sliders to change your settings. The meter at right shows the effect the changes will have on the likelihood that you'll reach your Desired Income target.' The interface features four sliders: 'Desired Income' (€2,000 per month), 'Minimum Income' (€1,500 per month), 'Voluntary Contributions' (€0 per month), and 'Retirement Age' (65 years). To the right, a gauge shows the 'Likelihood of achieving your desired income' at 86%. A 'SAVE THESE SETTINGS' button is present, with a note: 'You will have an opportunity to review these settings before submitting them.' At the bottom, there is a 'Reset to original settings' link and a section for 'Additional planning considerations'.
